

Using React, Laravel & Inertia:

<https://laravel.com/docs/11.x/frontend>

- . If not already known, using the chosen technologies means we are using a MVC architecture, similar to what we have done in the past but so much more advanced
- . A model is used to represent a database table, it makes sure the data created, retrieved, updated or deleted reflects the table's structure
- . A view is the frontend, it is how we render information from the backend & give it a fancy looking UI
- . A controller is how we get information stored onto the database ready to be sent to the view, we can query database tables & send the data back in the expected data type or structure
- . controller function validates data, uses the model to send, update, create or delete validated data to the right place, controller then sends the data to the view

Points to consider:

- . Offers full stack experience, meaning frontend, backend & middleware
- . Includes routing, validation, caching, queues, file storage
- . Can either write frontend in a JavaScript library, we are using React or wrap it in PHP
- . When you make the project, you can choose between starter kits with these being breeze & jetstream
- . Breeze is lightweight
- . Jetstream is more for using PHP for frontend
- . React will let us take advantage of JavaScript packages available from NPM
- . React by itself leaves many problems with passing data between both frontend & backend frameworks
- . Inertia will help us get past this, it lets us send data from backend to frontend without issues, it handles this itself
- . In a controller send information using Inertia
- . The easiest way to start a project is using Laravel breeze, this allows us to have a basic starting point with authentication pre-configured

Conclusion:

After reading through this page on the basics, I have an idea on how we should use these technologies...

I think for starters, we should go with Laravel Breeze. This means that we have a lightweight foundation for our project giving us a clear starting point, also authentication is pre-configured which means we can use it or build upon it to be used in our own way. In addition to Laravel Breeze we should use React with Inertia, we already came to the assumption this is what we would use but after reading through this I think it is good for our use case. It gives us flexibility in how the frontend can look, giving us the ability to

use bootstrap as well as JavaScript library's which will look much better than using PHP. Inertia makes the frontend & backend interact without us having to do extra work so it's a no brainer using it.

The most important take away from reading this is the difference of using blade & using react. I was not aware there were multiple ways of doing frontend but still after thinking about it react is better for our use case. There may be a way to use blade in certain scenarios & is something we should research & consider but for the most part react will serve us better.
